An Approximation Algorithm for
Box Abstraction of Transition Systems on
Real Vector Fields
(This is a revised version of a paper presented in SICE2009.)

## Kunihiko HIRAISHI and Koichi KOBAYASHI, JAIST

## Predicate abstraction for Hybrid Systems

- Predicate abstraction is a powerful technique for extracting finitestate models from infinite-state systems.
- Predicate abstraction has also been applied to the verification of hybrid systems [Alur00,Alur02,Alur06].
- Given a hybrid system with linear dynamics and a set of linear predicates, the verifier performs a search of the finite discrete quotient whose states correspond to the truth assignments to the input predicates.
- We propose a technique that can be used for accelerating the computation of abstract state spaces for hybrid systems.

## Predicate abstraction: example (1)

$$
\begin{aligned}
& \alpha=0.8, \\
& \beta=1 / 6\left(x_{1} \leq 0, x_{2}>0\right) ; \\
& \beta=-1 / 6\left(x_{1}>0, x_{2}>0\right) ; \\
& \beta=1 / 8\left(x_{1} \leq 0, x_{2} \leq 0\right) ; \\
& \beta=-1 / 8\left(x_{1}>0, x_{2} \leq 0\right) .
\end{aligned}
$$

A PieceWise Linear System

## Predicate abstraction: example (2)

> Predicates $\Pi=\left\{\pi_{i}\right\}$
> $x_{1} \leq k(k=-1,0,1)$,
> $x_{2} \leq k(k=-1,0,1)$.

Abstract states $B$
$S_{1}=[1,1,1,1,1,1], \ldots$,
$S_{10}=[0,1,1,0,0,1], \ldots$,
$S_{16}=[0,0,0,0,0,0]$.

## Transitions

$S_{10} \rightarrow S_{11} \equiv$
$\exists x \in S_{10} \exists x^{\prime} \in S_{11} . x \rightarrow x^{\prime}$ (over-approximation)

## Exact computation

```
b(\mp@subsup{v}{1}{},\ldots,\mp@subsup{v}{n}{})\mathrm{ : an abstract states with state variables }\mp@subsup{v}{1}{},\ldots,\mp@subsup{v}{n}{}
C}\mp@subsup{C}{\Pi}{(b)\subseteq\mp@subsup{\mathbf{R}}{}{n}}\mathrm{ : Concretization of }
\pi(R)\in{0,1} m}\mathrm{ : Discretization of region }
Im(R)\subseteq\mp@subsup{\mathbf{R}}{}{n}\mathrm{ : Image of region }R
Im}(b):=\pi(Im(\mp@subsup{C}{\Pi}{}(b))): Discretized Image of abstract state b
```

$$
\Delta\left(v_{1}, \cdots, v_{n}, v_{1}^{\prime}, \cdots, v_{n}^{\prime}\right):=\underset{b \in B}{\vee}\left(b\left(v_{1}, \cdots, v_{n}\right) \wedge \operatorname{Im}_{\Pi}(b)\left(v_{1}^{\prime}, \cdots, v_{n}^{\prime}\right)\right)
$$

## Approximated computation (1)

Enlarged abstract states $\underline{B}=\left\{\underline{b}_{i}\right\}$
$\underline{b}_{1}=[1,1,1, d c, d c, d c]$ $d c: d o n ’ t$ care

$$
\underline{b}_{2}=[d c, d c, d c, 1,1,1]
$$

$$
S_{1}=\underline{b}_{1} \wedge \underline{b}_{2}
$$

Conjunction complete: Each abstract state is represented by conjunction of enlarged abstract states.

## Approximated computation (2)

$\underline{b}\left(v_{1}, \ldots, v_{n}\right)$ : enlarged abstract state with state variables $v_{1}, \ldots, v_{n}$ $\underline{B}$ : the set of enlarged abstract states $\operatorname{Im}_{\Pi}\left(C_{\Pi}(\underline{b})\right)$ : discretized image of $\underline{b}$

$$
\Delta \sim\left(v_{1}, \cdots, v_{n}, v_{1}^{\prime}, \cdots, v_{n}^{\prime}\right):=\bigwedge_{\underline{b} \in \underline{B}}^{\wedge}\left(\underline{b}\left(v_{1}, \cdots, v_{n}\right) \rightarrow \operatorname{Im}_{\Pi}(\underline{b})\left(v_{1}^{\prime}, \cdots, v_{n}^{\prime}\right)\right)
$$

## Justification of the Idea (1)

- Discrete-time autonomous system: $x\left(t_{k+1}\right)=f\left(x\left(t_{k}\right)\right)$.
- If $f$ is injective (one-to-one), then $\operatorname{Im}\left(Q_{1} \cap Q_{2}\right)=\operatorname{Im}\left(Q_{1}\right) \cap \operatorname{Im}\left(Q_{2}\right)$. [This holds for discrete-time linear/affine systems.]
- Even if $\operatorname{Im}\left(Q_{1} \cap Q_{2}\right)=\operatorname{Im}\left(Q_{1}\right) \cap \operatorname{Im}\left(Q_{2}\right), \pi\left(\operatorname{Im}\left(Q_{1} \cap Q_{2}\right)=\pi\left(\operatorname{Im}\left(Q_{1}\right)\right) \cap\right.$ $\pi\left(\operatorname{Im}\left(Q_{2}\right)\right)$ does not necessarily hold (discretization error).
- However, the error occurs only around correct boxes.
- If $\left\|f^{-1}\left(x_{1}\right)-f^{-1}\left(x_{2}\right)\right\| /\left\|x_{1}-x_{2}\right\| \leq K$ for any $x_{1}, x_{2}$ (Lipschitz continuity of $f^{-1}$ ), then $\left\|x_{1}-x_{2}\right\| \leq K\left\|f\left(x_{1}\right)-f\left(x_{2}\right)\right\|$. [This holds for discrete-time linear/affine systems.]
- Suppose that $x_{1} \in Q_{1}-Q_{2}, x_{2} \in Q_{2}-Q_{1}$, but $f\left(x_{1}\right)$ and $f\left(x_{2}\right)$ are in the same box.
- Then, there exists a positive real $R$ s.t. $\left\|f\left(x_{1}\right)-f\left(x_{2}\right)\right\| \leq R$.
- We have $\left\|x_{1}-x_{2}\right\| \leq K R$.

## Justification of the Idea (2)

DES2010, Dec. Nagoya

## Complexity

- $h_{i}$ : the number of predicates in the $i$-th axis.
- The number of abstract states is

$$
|B|=\Pi_{i=1, n}\left(h_{i}+1\right)=O\left((1+m / n)^{n}\right) .
$$

- The number of enlarged abstract states is

$$
|\underline{B}|=\Sigma_{i=1, n}\left(h_{i}+1\right)=O(m+n) .
$$

## Discretization of Polyhedra: <br> how to compute $\operatorname{Im}_{\Pi}(\underline{b})$ from $\operatorname{Im}\left(\mathrm{C}_{\Pi}(\underline{b})\right)$

- Since $\operatorname{Im}\left(C_{\Pi}(\underline{b})\right)$ is much larger than $\operatorname{Im}\left(C_{\Pi}(b)\right)$, the approximated computation requires more time at this step, provided that the computation time for the discretization depends on the size of polyhedra. As a result, the approximated computation is not very fast.
- We have develop an efficient algorithm, called the beam method, for this step. The algorithm uses convexity of regions.
- The beam method is compared with
- Direct comparison : computing intersection between polyhedron $P$ and each box in the axis-aligned bounding box of $P$,
- Shannon expansion.

## Beam Method for 2D Space

## Systems with Inputs

$$
\begin{aligned}
& x\left(t_{k+1}\right)=A x\left(t_{k}\right)+B u\left(t_{k}\right) \\
& \binom{x\left(t_{k+1}\right)}{u}=\left(\begin{array}{l|l}
A & B \\
\hline 0 & I
\end{array}\right)\binom{x\left(t_{k}\right)}{u}
\end{aligned}
$$

We embed the input in the state space. Then the matrix is nonsingular, provided that $A$ is nonsingular.

## Computation Results (1)

$$
x\left(t_{k+1}\right)=A x\left(t_{k}\right)+\left(\begin{array}{c}
-0.1 \\
\vdots \\
-0.1
\end{array}\right)
$$

where $A$ is an $n$-dimensional square matrix that represents the following rotations:
$n=2: \pi / 3$ around the origin.
$n=3: \pi / 3$ around the origin on $x_{23}$-plane, $x_{13}$-plane, and $x_{12}$-plane.
$n=4: \pi / 3$ around the origin on $x_{12}$-plane, $x_{23}$-plane, and $x_{31}$-plane.
$n=5: \pi / 3$ around the origin on $x_{12}$-plane, $x_{23}$-plane, $x_{34}$-plane, and $x_{45^{-}}$ plane.

## Computation Results (2)

- $\tau_{\Pi}$ : the exact transitions.
- $\tau_{\Pi} \sim$ : the approximated transitions.
- Evaluation criteria:
- Ratio $\gamma^{\sim}=\left|\tau_{\Pi}^{\sim}\right| /\left|\tau_{\Pi}\right|$.
- The number of error transitions classified by hamming distance. Let $\# e_{i}$ be the number of transitions in $\tau_{\Pi}{ }^{\sim}-H_{i}\left(\tau_{\Pi}\right)$, where $H_{i}\left(\tau_{\Pi}\right)$ is the set of all transitions whose hamming distance to at least one of transitions in $\tau_{\Pi}$ is no more than $i$.
